

Questions for discussion

- Consistency between co-emitted species.
How important is this and how do we ensure consistency?
- Consistency of vegetation maps used. Use of vegetation maps in various models.
- Connection between emissions and models.
Can we improve the "interface" between produced emissions and what models require?
- Emissions that are not covered. Are we missing important elements?

Co-emitted species: need studies for sectors and countries

How can we use information on co-emitted species to infer CO₂/CH₄ emissions?

Some examples in WP2 and WP5 already discussed yesterday

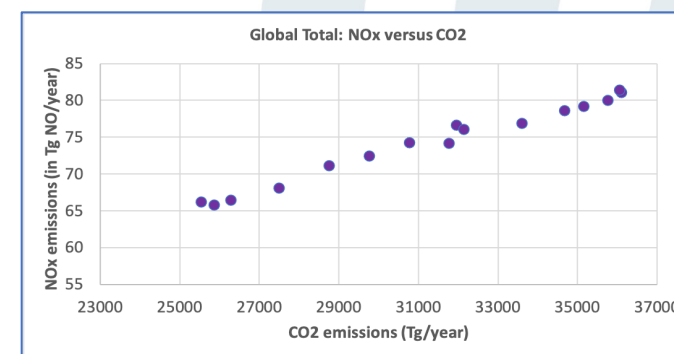

Are the emissions of some species well correlated?

Example using EDGAR5 emissions for CO₂, CO and NO_x

CO versus CO₂
All sectors
→ No correlation

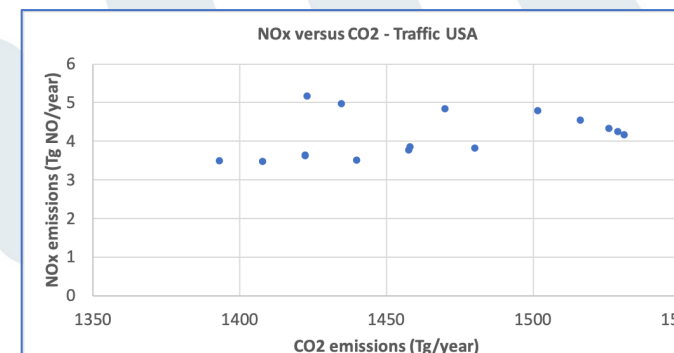

CO versus CO₂
Traffic USA
→ No correlation

NO_x versus
CO₂

All sectors → Looks
rather correlated

NO_x versus
CO₂

Traffic USA
All sectors
→ Not correlated

Needs a lot of work: no correlation on a global or country basis does not mean that there is no correlation on small scale or for sub-sectors. Technological changes need also to be taken into account accurately

Co-emitted species: need studies for sectors and countries

A few publications discussing co-emitted species:

Sadiq et al., ACP, 2021: Understanding the influence of combustion on atmospheric CO₂ over Europe by using satellite observations of CO₂ and reactive trace gases

Zheng et al, Sciences Advances, 2021: Satellite-based estimates of decline and rebound in China's CO₂ emissions during COVID-19 pandemic

Reuter et al., ACP, 2019: Towards monitoring localized CO₂ emissions from space: co-located regional CO₂ and NO₂ enhancements observed by the OCO-2 and S5P sate

Silva and Arellano, Remote Sensing, 2107: Characterizing Regional-Scale Combustion Using Satellite Retrievals of CO, NO₂ and CO₂.

This paper considers both anthropogenic and fire emissions

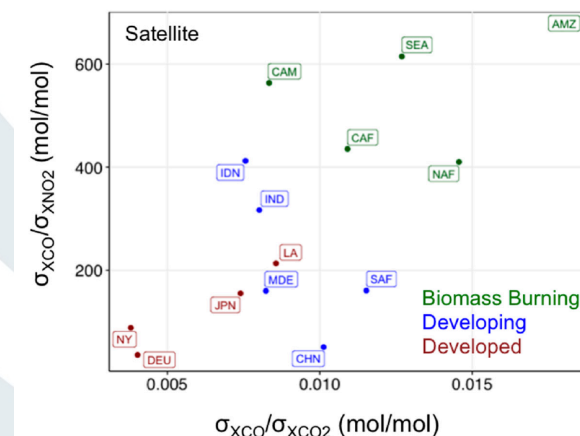

And several other papers....

a) Combustion NO_x:CO₂ ratio (x10⁻³)

Consistency between co-emitted species

Global non-EU CoCO2 power plant point source database:

- Emissions for co-emitted species (e.g., NO_x, SO₂) estimated using average emission ratios per fuel type derived from approx. 2,000 USA power plants
- Information on the spread of the ratios could be provided for uncertainty estimates

NO_x/CO₂ emission ratios

SO₂/CO₂ emission ratios

Vegetation maps

Which vegetation maps are used in CoCO2? Are the datasets used in CoCO2 and CAMS consistent, for example for the emissions from fires (GFAS) and the natural emissions of BVOCs (CAMS-GLOB-BIO)

Are the currently available vegetation maps consistent?

Work done within the CAMS project on emissions and in Sindelarova et al. (ESSD, 2021): differences between several vegetation datasets.

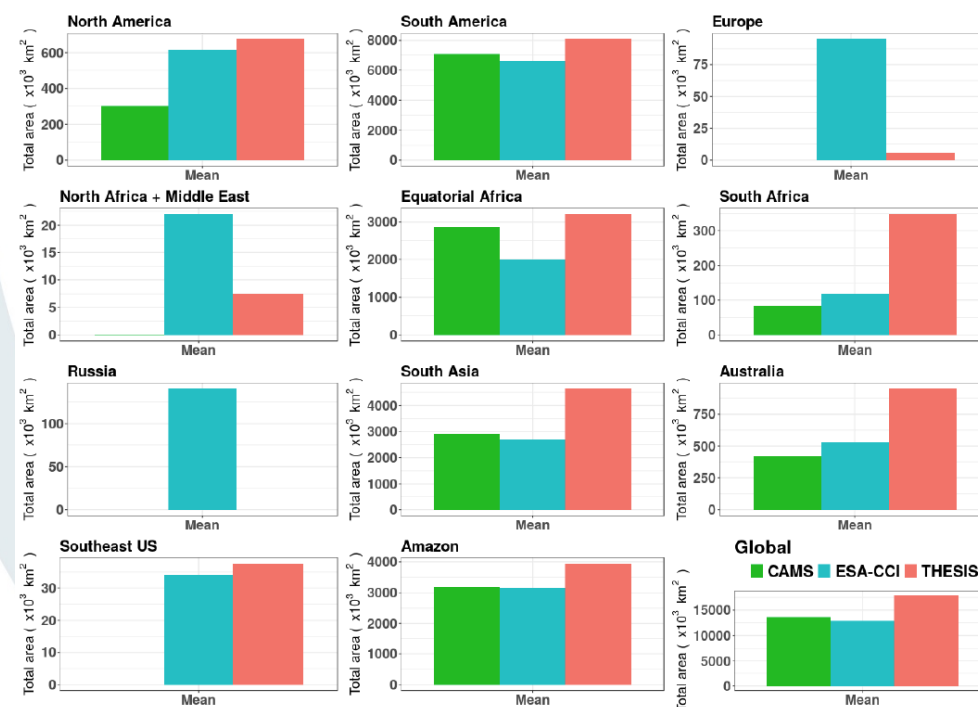

Other studies:

Liu et al., IJRS 2018: Comparison of country-level cropland areas between ESA-CCI land cover maps and FAOSTAT data

Paper by Hua et al. (Remote Sensing, 2018): Spatial Consistency Assessments for Global Land-Cover Datasets: A Comparison among GLC2000, CCI LC, MCD12, GLOBCOVER and GLCNMO

And others...

Broadleaf Evergreen Tree - Total area

Connection between emissions and models

Prior information

- Annual/monthly gridded emissions

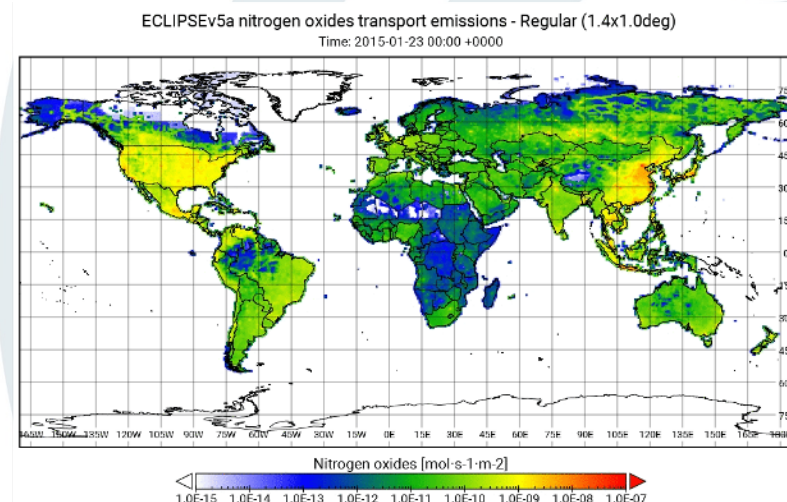

- Temporal profiles
- Vertical profiles
- Speciation profiles (e.g. NO_x to NO / NO₂)

Processing

Offline emission processing systems

- HERMESv3 (Guevara et al. 2019)
- SMOKE (Baek and Seppanen, 2018)

Emission input for models

Online emission processing systems

- HEMCO 3.0 (Lin et al., 2021) – implemented in GEOS-Chem, NASA GEOS, NOAA UFS models
- Jähn et al. (2020) – implemented in COSMO-GHG and COSMOART
- + several in-house processing systems...

Connection between emissions and models

- Vertical/Temporal profiles typically provided per sector...
- But more detailed profiles are needed to take into account effects of e.g. different sociodemographic patterns, climatological/meteorological conditions, stack properties

Vertical distribution for As Ponter power plant (January 2015)

Vertical distribution for As Ponter power plant (July 2015)

Weekly factors road traffic

Hourly factors road traffic (weekdays)

Hourly factors road traffic (Saturdays)

Connection between emissions and models

- The level of detail of the vertical/temporal profiles (e.g. country-dependent, point source-dependent) is directly linked to the level of flexibility of the emission pre-processing system
- Meteorological parametrisations (e.g., plume rise calculation) → Can be provided off line for past years, but need to be implemented online for forecasting purposes
- Are all these details in the emissions needed? (not all current models can use them)
- Which topic should be made a priority? – or where do we have more room for improvement in the models? Which links to....
- How we quantify the impact of using more detailed temporal/vertical profiles? (sometimes measurements to evaluate these aspects are scarce)
